COMPLEXES OF MODULES OVER EXCEPTIONAL LIE SUPERALGEBRAS $E(3,8)$ AND $E(5,10)$.

VICTOR G. KAC* AND ALEXEI RUDAKOV

Abstract. In this paper complexes of generalized Verma modules over the infinite-dimensional exceptional Lie superalgebras $E(3,8)$ and $E(5,10)$ are constructed and studied.

0. Introduction.

In our papers [KR1]–[KR3] we constructed all degenerate irreducible modules over the exceptional Lie superalgebra $E(3,6)$. In the present paper we apply the same method to the exceptional Lie superalgebras $E(3,8)$ and $E(5,10)$.

The Lie superalgebra $E(3,8)$ is strikingly similar to $E(3,6)$. In particular, as in the case of $E(3,6)$, the maximal compact subgroup of the group of automorphisms of $E(3,8)$ is isomorphic to the group of symmetries of the Standard Model. However, as the computer calculations by Joris van Jeugt show, the fundamental particle contents in the $E(3,8)$ case is completely different from that in the $E(3,6)$ case [KR2]. All the nice features of the latter case, like the CPT symmetry, completely disappear in the former case. We believe that the main reason behind this is that, unlike $E(3,6)$, $E(3,8)$ cannot be embedded in $E(5,10)$, which, we believe, is the algebra of symmetries of the SU_5 Grand Unified Model (the maximal compact subgroup of the automorphism group of $E(5,10)$ is SU_5).

However, similarity with $E(3,6)$ allows us to apply to $E(3,8)$ all the arguments from [KR2] almost verbatim, and Figure 1 of the present paper that depicts all degenerate $E(3,8)$-modules is almost the same as Figure 3 from [KR2] for $E(3,6)$.

The picture in the $E(5,10)$ case is quite different (see Figure 2). We believe that it depicts all degenerate irreducible $E(5,10)$-modules, but we still do not have a proof.

1. Morphisms between generalized Verma modules.

Let $L = \oplus_{j\in\mathbb{Z}}\mathfrak{g}_j$ be a $\mathbb{Z}$-graded Lie superalgebra by finite-dimensional vector spaces. Let

$$L_- = \oplus_{j<0}\ \mathfrak{g}_j,\ \ L_+ = \oplus_{j>0}\ \mathfrak{g}_j,\ \ L_0 = \mathfrak{g}_0 + L_+\,.$$

Given a $\mathfrak{g}_0$-module V, we extend it to a L_0-module by letting L_+ act trivially, and define the induced L-module

$$M(V) = U(L)\otimes_{U(L_0)} V\,.$$

If V is a finite-dimensional irreducible $\mathfrak{g}$-module, the L-module $M(V)$ is called a *generalized Verma module* (associated to V), and it is called *degenerate* if it is not irreducible.

* Supported in part by NSF grant DMS-9970007.

Let A and B be two $\mathfrak{g}_0$-modules and let $\mathrm{Hom}(A,B)$ be the $\mathfrak{g}_0$-module of linear maps from A to B. The following proposition will be extensively used to construct morphisms between the L-modules $M(A)$ and $M(B)$.

Proposition 1.1. *Let $\Phi \in M(\mathrm{Hom}(A,B))$ be such that*

$$v \cdot \Phi = 0 \text{ for all } v \in L_0\,. \tag{1.1}$$

Then we can construct a well-defined morphism of L-modules

$$\varphi : M(A) \to M(B)$$

by the rule $\varphi(u \otimes a) = u\,\Phi(a)$. Explicitly, write $\Phi = \sum_m u_m \otimes \ell_m$, where $u_m \in U(L)$, $\ell_m \in \mathrm{Hom}(A,B)$. Then

$$\varphi(u \otimes a) = \sum_m (uu_m) \otimes \ell_m(a)\,. \tag{1.2}$$

Proof. We have to prove that for $v \in U(L_0)$,

$$\varphi(uv \otimes a) = \varphi(u \otimes va)\,,$$

in order to conclude that φ is well-defined. Notice that condition (1.1) means

$$\sum_m [v,u_m] \otimes \ell_m + \sum_m u_m \otimes v\ell_m = 0\,. \tag{1.3}$$

Therefore we have:

$$\begin{aligned}
\varphi(uv \otimes a) &= \sum_m uvu_m \otimes \ell_m(a) \\
&= \sum_m u[v,u_m] \otimes \ell_m(a) + \sum_m uu_m v \otimes \ell_m(a) \\
&= \sum_m u[v,u_m] \otimes \ell_m(a) + \sum_m uu_m \otimes v(\ell_m(a)) \\
&= \sum_m u[v,u_m] \otimes \ell_m(a) + \sum_m uu_m \otimes (v\ell_m)(a) + \sum_m uu_m \otimes \ell_m(va) \\
\text{(by (1.3) and (1.2))} &= \sum uu_m \otimes \ell_m(va) \;=\; \varphi(u \otimes va)\,.
\end{aligned}$$

The fact that φ defines a morphism of L-modules is immediate from the definition. □

Remark 1.1. If L_0 is generated by $\mathfrak{g}_0$ and a subset of $T \subset L_+$, then condition (1.1) is equivalent to

$$\mathfrak{g}_0 \cdot \Phi = 0 \tag{1.4a}$$

$$a \cdot \Phi = 0 \text{ for all } a \in T\,. \tag{1.4b}$$

Condition (1.4a) usually gives a hint to a possible shape of Φ and is checked by general invariant-theoretical considerations. After that (1.4b) is usually checked by a direct calculation.

Remark 1.2. We can view $M(V)$ also as the induced $(L_- \oplus \mathfrak{g}_0)$-module: $U(L_- \oplus \mathfrak{g}_0) \otimes_{U(\mathfrak{g}_0)} V$. Then condition (1.4a) on $\Phi = \sum_m u_m \otimes \ell_m$, where $u_m \in U(L_- \oplus \mathfrak{g}_0)$, $\ell_m \in \mathrm{Hom}(A,B)$, suffices in order (1.2) to give a well-defined morphism of $(L_- \oplus \mathfrak{g}_0)$-modules. One can also replace $\mathfrak{g}_0$ by any of its subalgebras.

2. Lie superalgebras $E(3,6)$, $E(3,8)$ and $E(5,10)$.

Recall some standard notation:

$$W_n = \{\sum_{j=1}^{n} P_i(x)\partial_i \mid P_i \in \mathbb{C}[[x_{\bar{1}}, \dots, x_n]],\ \partial_i \equiv \partial/\partial x_i\}$$

denotes the Lie algebra of formal vector fields in n indeterminates:

$$S_n = \{D = \sum P_i\partial_i \mid divD \equiv \sum_i \partial_i P_i = 0\}$$

denotes the Lie subalgebra of divergenceless formal vector fields; $\Omega^k(n)$ denotes the associative algebra of formal differential forms of degree k in n indeterminates, $\Omega^k_{c\ell}(n)$ denoted the subspace of closed forms.

The Lie algebra W_n acts on $\Omega^k(n)$ via Lie derivative $D \to L_D$. Given $\lambda \in \mathbb{C}$ one can twist this action:

$$D\,\omega = L_D\,\omega + \lambda(divD)\,\omega\,.$$

The W_n-module thus obtained is denoted by $\Omega^k(n)^\lambda$. Recall the following obvious isomorphism of W_n-modules

$$\Omega^0(n) \simeq \Omega^n(n)^{-1}\,, \tag{2.1}$$

and the following slightly less obvious isomorphism of W_n-modules

$$W_n \simeq \Omega^{n-1}(n)^{-1}\,. \tag{2.2}$$

The latter is obtained by mapping a vector field $D \in W_n$ to the $(n-1)$-form $\iota_D(dx_1\wedge\ldots\wedge dx_n)$. Note that (2.2) induces an isomorphism of S_n-modules:

$$S_n \simeq \Omega^{n-1}_{c\ell}(n)\,. \tag{2.3}$$

Recall that the Lie superalgebra $E(5,10) = E(5,10)_{\bar{0}} + E(5,10)_{\bar{1}}$ is constructed as follows [K], [CK]:

$$E(5,10)_{\bar{0}} = S_5, \quad E(5,10)_{\bar{1}} = \Omega^2_{c\ell}(5),$$

$E(5,10)_{\bar{0}}$ acts on $E(5,10)_{\bar{1}}$ via the Lie derivative, and $[\omega_2, \omega_2'] = \omega_2 \wedge \omega_2' \in \Omega^4_{c\ell}(5) = S_5$ (see (2.3)) for $\omega_2, \omega_2' \in E(S,10)_{\bar{1}}$.

Next, recall the construction of the Lie superalgebras $E^\flat := E(3,6)$ and $E^\sharp := E(3,8)$ [CK]:

$$\begin{aligned} E^\flat_{\bar{0}} &= E^\sharp_{\bar{0}} = W_3 + s\ell_2(\Omega^0(3)) \ \text{ (the natural semidirect sum)}\,; \\ E^\flat_{\bar{1}} &= \Omega^1(3)^{-1/2} \otimes \mathbb{C}^2, \ \ E^\sharp_{\bar{1}} = (\Omega^0(3)^{-1/2} \otimes \mathbb{C}^2) + (\Omega^2(3)^{-1/2} \otimes \mathbb{C}^2)\,. \end{aligned}$$

The action of the even on the odd parts is defined via the Lie derivative and the multiplication of a function and a differential form. The bracket of two odd elements is defined by using the identifications (2.1) and (2.2) as follows. For $\omega_i, \omega_i' \in \Omega^i(3)$ and $v, v' \in \mathbb{C}^2$ one defines the following bracket of two elements from $E^\flat_{\bar{1}}$:

$$[\omega_1 \otimes v, \omega_1' \otimes v'] = -(\omega_1 \wedge \omega_1') \otimes (v \wedge v') - (d\omega_1 \wedge \omega_1' + \omega_1 \wedge d\omega_1') \otimes (v \cdot v')\,, \tag{2.4}$$

and the following bracket of two elements from $E^\sharp_{\bar{1}}$:

$$\begin{aligned} [\omega_2 \otimes v, \omega_2' \otimes v'] &= 0, \ \ [\omega_0 \otimes v, \omega_0' \otimes v'] = -(d\omega_0 \wedge d\omega_0') \otimes (v \wedge v'), \\ [\omega_0 \otimes v, \omega_2 \otimes v'] &= -(\omega_0 \wedge \omega_2) \otimes (v \wedge v') - (d\omega_0 \wedge \omega_2 - \omega_0 \wedge \omega_2) \otimes (v \cdot v'))\,. \end{aligned} \tag{2.5}$$

Recall also an embedding of $E^\flat$ in $E(5,10)$ [CK], [KR2]. For that let $z_+ = x_4$, $z_- = x_5$, $\partial_+ = \partial_4$, $\partial_- = \partial_5$, and let ϵ^+, ϵ^- denote the standard basis of $\mathbb{C}^2$. Then $E_0^\flat$ is embedded in $E(5,10)_0 = S_5$ by ($D \in W_3, a, b, c \in \Omega^0(3)$):

(2.6)

$$D \mapsto D - \tfrac{1}{2}(divD)(z_+\partial_+ + z_-\partial_-),\ \begin{pmatrix} a & b \\ c & -a \end{pmatrix} \mapsto a(z_+\partial_+ - z_-\partial_-) + bz_+\partial_- + cz_-\partial_+ ,$$

and $E_{\bar{1}}^\flat$ is embedded in $E(5,10)_{\bar{1}} = \Omega^2_{c\ell}(5)$ by ($f \in \Omega^0(3)$):

$$f\,dx_i \otimes \epsilon^\pm \mapsto z_\pm\,dx_i \wedge df + f\,dx_i \wedge dz_\pm . \tag{2.7}$$

Introduce the following subalgebras $S^\flat \subset E^\flat$ and $S^\sharp \subset E^\sharp$:

$$\begin{aligned} S_{\bar{0}}^\flat &= S_{\bar{0}}^\sharp = W_3 + \mathbb{C} \otimes s\ell_2(\mathbb{C}) , \\ S_{\bar{1}}^\flat &= \Omega^1_{c\ell}(3)^{-1/2} \otimes \mathbb{C}^2 ,\ S_{\bar{1}}^\sharp = \Omega^0(3)^{-1/2} \otimes \mathbb{C}^2 . \end{aligned}$$

Proposition 2.1. *The map $S^\sharp \to S^\flat$, which is identical on $S_{\bar{0}}^\sharp$ and sends $f \otimes v \in S_{\bar{1}}^\sharp$ to $df \otimes v \in S_{\bar{1}}^\flat$ is a surjective homomorphism of Lie superalgebras with 2-dimensional central kernel $\mathbb{C} \otimes \mathbb{C}^2 \subset S_{\bar{1}}^\sharp$.*

Proof. It is straightforward using (2.4) and (2.5). □

This proposition is probably the main reason for a remarkable similarity between representation theories of $E^\sharp$ and $E^\flat$. We shall stress this similarity in our notation and develop representation theory of $E^\sharp$ along the same lines as that of $E^\flat$ done in [KR1], [KR2]. Sometimes we shall drop the superscript $\flat$ or $\sharp$ when the situation is the same.

Recall that $E^\flat$ carries a unique irreducible consistent $\mathbb{Z}$-gradation. It has depth 2, and it is defined by:

$$\deg x_i = -\deg \partial_i = 2 ,\ \deg \partial_i = -1 ,\ \deg \epsilon^\pm = 0 ,\ \deg s\ell_2(\mathbb{C}) = 0 . \tag{2.8}$$

The "non-positive" part of this $\mathbb{Z}$-gradation is as follows:

$$\begin{aligned} \mathfrak{g}_{-2} &= \langle \partial_i \,|i = 1,2,3\rangle ,\ \mathfrak{g}_{-1} = \langle d_i^a := \epsilon^a \otimes dx_i = dx_i \wedge dz_a \,|i = 1,2,3, a = +,-\rangle , \\ \mathfrak{g}_0 &= s\ell_3(\mathbb{C}) \oplus s\ell_2(\mathbb{C}) \oplus CY , \end{aligned}$$

where

$$\begin{aligned} s\ell_3(\mathbb{C}) &= \langle h_1 = x_1\partial_1 - x_2\partial_2,\ h_2 = x_2\partial_2 - x_3\partial_3,\ e_1 = x_1\partial_2, \\ &\qquad e_2 = x_2\partial_3,\ e_{12} = x_1\partial_3,\ f_1 = x_2\partial_1,\ f_2 = x_3\partial_2,\ f_{12} = x_3\partial_1\rangle , \end{aligned} \tag{2.9}$$

$$s\ell_2(\mathbb{C}) = \langle h_3 = z_+\partial_+ - z_-\partial_-,\ e_3 = z_+\partial_-,\ f_3 = z_-\partial_+\rangle , \tag{2.10}$$

$$Y = \tfrac{2}{3}\sum x_i\partial_i - (z_+\partial_+ + z_-\partial_-) . \tag{2.11}$$

The eigenspace decomposition of $\mathrm{ad}\,(3Y)$ coincides with the consistent $\mathbb{Z}$-grading of $E^\flat$. We fix the Cartan subalgebra $\mathcal{H} = \langle h_1, h_2, h_3, Y\rangle$ and the Borel subalgebra $\mathcal{B} = \mathcal{H} + \langle e_i,\ (i = 1,2,3),\ e_{12}\rangle$ of $\mathfrak{g}_0$. Then $f_0 := d_1^+$ is the highest weight vector of the (irreducible) $\mathfrak{g}_0$-module $\mathfrak{g}_{-1}$, the vectors

$$e_0' := x_3 d_3^- \ \text{ and } \ e_0^\flat := x_3 d_2^- - x_2 d_3^- + 2z_- dx_2 \wedge dx_3$$

are all the lowest weight vectors of the $\mathfrak{g}_0$-module $\mathfrak{g}_1$, and one has:

$$[e'_0, f_0] = f_2\,, \tag{2.12}$$

$$[e^\flat_0, f_0] = \tfrac{2}{3}h_1 + \tfrac{1}{3}h_2 - h_3 - Y =: h^\flat_0\,, \tag{2.13}$$

so that

$$h^\flat_0 = -x_2\partial_2 - x_3\partial_3 + 2z_-\partial_-\,.$$

The following relations are also important to keep in mind:

$$[\,e'_0, d^+_1] = f_2, \quad [e'_0, d^+_2] = -f_{12}, \ [e'_0, d^+_3] = 0, \ [e'_0, d^-_i] = 0\,, \tag{2.14}$$

$$[\,d^\pm_i, d^\pm_j] = 0\,, \qquad [d^+_i, d^-_j] + [d^+_j, d^-_i] = 0\,. \tag{2.15}$$

Recall that $\mathfrak{g}_0$ along with the elements f_0, $e^\flat_0$, e'_0 generate the Lie superalgebra $E^\flat$ [CK].

The Lie superalgebra $E^\sharp$ carries a unique consistent irreducible $\mathbb{Z}$-gradation of depth 3:

$$E^\sharp = \oplus_{j\geq -3}\ \mathfrak{g}_j\,.$$

It is defined by:

$$\deg x_i = -\deg\partial_i = \deg\, dx_i = 2, \ \deg\epsilon^\pm = -3, \ \deg s\ell_2(\mathbb{C}) = 0\,. \tag{2.16}$$

In view of Proposition 2.1 and the above $E^\flat$-notation, we introduce the following $E^\sharp$-notation:

$$\begin{aligned} d^\pm &:= 1\otimes\epsilon^\pm,\ d^\pm_i := x_i\otimes\epsilon^\pm,\ e'_0 := \tfrac{1}{2}x_3^2\otimes\epsilon^\pm,\ f_0 := d^+_1\,,\\ e^\sharp_0 &:= -(dx_2\wedge dx_3)\otimes\epsilon^-,\ \ h^\sharp_0 := \tfrac{2}{3}h_1 + \tfrac{1}{3}h_2 - \tfrac{1}{2}h_3 + \tfrac{1}{2}Y\,. \end{aligned} \tag{2.17}$$

If, in analogy with $E^\flat$, we denote $\epsilon^a = dz_a$, then $\mathfrak{g}_{-3} = \langle dz_+, dz_-\rangle$, $\mathfrak{g}_{-2}$, $\mathfrak{g}_{-1}$ and $\mathfrak{g}_0$ are the same as for $E^\flat$ (except that now $[\mathfrak{g}_{-1}, \mathfrak{g}_{-2}] \neq 0$), and the relations (2.12), (2.13), (2.14), (2.15) still hold, but the formula for h_0 is different:

$$h^\sharp_0 = \tfrac{2}{3}h_1 + \tfrac{1}{3}h_2 - \tfrac{1}{2}h_3 + \tfrac{1}{2}Y = x_1\partial_1 - z_+\partial_+\,. \tag{2.18}$$

As in the $E^\flat$ case, the elements e_i, f_i, h_i for $i = 0, 1, 2, 3$ along with e'_0 generate $E^\sharp$, the elements $e^\sharp_0$ and e'_0 are all lowest weight vectors of the $\mathfrak{g}_0$-module $\mathfrak{g}_1$, and $\mathfrak{g}_0$ along with e'_0 and $e^\sharp_0$ generate the subalgebra $\oplus_{j\geq 0}\,\mathfrak{g}_j$ [CK]. Thus, by Remark 1.1, condition (1.4b) is equivalent to

$$e'_0\cdot\Phi = 0 \quad \text{and} \quad e^\sharp_0\cdot\Phi = 0\,. \tag{2.19}$$

3. **Complexes of degenerate Verma modules over $E(3,6)$.**

Let W be a finite-dimensional symplectic vector space and let H be the corresponding Heisenberg algebra

$$H = T(W)/(v\cdot w - w\cdot v - (v,w)\cdot 1)$$

where $T(W)$ denotes the tensor algebra over W and $(\ ,\ )$ is the non-degenerate symplectic form on W. Given two transversal Lagrangian subspaces $L, L' \subset W$, we have a canonical isomorphism of symplectic spaces: $W = L + L' \simeq L\oplus L^*$, and we can canonically identify the symmetric algebra $S(L)$ with the factor of H by the left ideal generated by L':

$$V_L := H/(L') \simeq S(L)\mathbf{1}_L\,, \quad \text{where } \mathbf{1}_L = 1 + L'\,. \tag{3.1}$$

One thus acquires an H-module structure on $S(L)$.

We construct a symplectic space W by taking $x_1, x_2, x_3, z_+, z_-, \partial_1, \partial_2, \partial_3, \partial_+, \partial_-$ as a basis with the first half being dual to the second half:

$$(\partial_i, x_j) = -(x_j, \partial_i) = \delta_{ij}\,,\ (\partial_a, z_b) = -(z_b, \partial_a) = \delta_{a,b}\,,\ \text{ all other pairings zero.} \tag{3.2}$$

In general the decomposition $W = L + L' \simeq L \oplus L^*$ provides the canonical maps:

$$\mathrm{End}(L) \xrightarrow{\sim} L \otimes L^* \xrightarrow{\sim} L \cdot L' \hookrightarrow H\,,$$

which induce a Lie algebra homomorphism: $g\ell(L) \to H_{Lie}$, where the Lie algebra structure is defined by the usual commutator.

We consider the following subspaces of W:

$$\begin{array}{ll} L_A = L'_D = \langle x_i, z_a \rangle\,, & L_B = L'_C = \langle x_i, \partial_a \rangle\,, \\ L_C = L'_B = \langle \partial_c, z_a \rangle\,, & L_D = L'_A = \langle \partial_i, \partial_a \rangle\,, \end{array} \tag{3.3}$$

where $i = 1, 2, 3\,,\ a = +, -$. Note that these are the only $\mathfrak{g}_0$-invariant Lagrangian subspaces of W.

As formulae (2.9)–(2.11) determine the inclusion $\mathfrak{g}_0 \hookrightarrow g\ell(V_X)$, where $X = A$, B, C or D, we get a Lie algebra monomorphism:

$$\mathfrak{g}_0 \hookrightarrow \mathfrak{g}\ell(V_X) \hookrightarrow H_{Lie}\,. \tag{3.4}$$

Thus we get a $\mathfrak{g}_0$-action on V_X. Let us notice that by (3.4)

$$Y \to Y^\flat = \tfrac{2}{3}(\sum_i x_i\partial_i) - (\sum_a z_a\partial_a) \tag{3.5}$$

and

$$Y^\flat\,\mathbf{1}_A = 0\,,\ Y^\flat\,\mathbf{1}_B = 2\,\mathbf{1}_B\,,\ Y^\flat\,\mathbf{1}_C = -2\,\mathbf{1}_C\,,\ Y^\flat\,\mathbf{1}_D = 0\,,$$

as it should be for $E^\flat = E(3,6)$ (see [KR2]).

In the $E(3,8)$ case we modify the $\mathfrak{g}_0$-action on V_X leaving it the same for $s\ell_3(\mathbb{C}) \oplus s\ell_2(\mathbb{C}) \subset \mathfrak{g}_0$, but letting

$$Y \mapsto Y^\sharp = -\tfrac{4}{3}(\sum_i x_i\partial_i) + (\sum_a z_a\partial_a) = Y^\flat + 2T\,,\ \text{ where } T = -\sum_i x_i\partial_i + \sum_a z_a\partial_a\,. \tag{3.6}$$

We have got:

$$\begin{aligned} Y\,x_i^p z_a^r\,\mathbf{1}_A &= \left(-\tfrac{4}{3}p + r\right) x_i^p z_a^r\,\mathbf{1}_A\,, \\ Y\,x_i^p \partial_a^r\,\mathbf{1}_B &= \left(\tfrac{4}{3}p - r - 2\right) x_i^p \partial_a^r\,\mathbf{1}_B\,, \\ Y\,\partial_i^q z_a^r\,\mathbf{1}_C &= \left(\tfrac{4}{3}q + r + 4\right) \partial_i^q z_a^r\,\mathbf{1}_C\,, \\ Y\,\partial_i^q \partial_a^r\,\mathbf{1}_D &= \left(\tfrac{4}{3}q - r + 2\right) \partial_i^q \partial_a^r\,\mathbf{1}_D\,. \end{aligned}$$

Let $F(p,q;r;y)$ denote the finite-dimensional irreducible $\mathfrak{g}_0$-module with highest weight $(p,q;r;y)$, where $p,q,r \in \mathbb{Z}_+$, $y \in \mathbb{C}$, and let $M(p,q;r;y) = M(F(p,q;r;y))$ be the corresponding generalized Verma module over $E(3,8)$. This module has a unique irreducible quotient denoted by $I(p,q;r;y)$. The latter module is called degenerate if the former is.

We announce below a classification of all degenerate irreducible $E(3,8)$-modules.

Theorem 3.1. *All irreducible degenerate $E(3,8)$-modules $I(p,q;r,y)$ are as follows $(p,q,r\in\mathbb{Z}_+)$:*

$$\begin{aligned}
&\textit{type } A: \quad I(p,0;r;y_A)\,, \quad y_A=-\tfrac{4}{3}p+r\,;\\
&\textit{type } B: \quad I(p,0;r;y_B)\,, \quad y_B=-\tfrac{4}{3}p-r-2\,;\\
&\textit{type } C: \quad I(0,q;r;y_C)\,, \quad y_C=\tfrac{4}{3}q+r+4\,;\\
&\textit{type } D: \quad I(0,q;r;y_D)\,, \quad y_D=\tfrac{4}{3}q-r+2\,, \ \textit{and } (q,r)\neq(0,0),\,.
\end{aligned}$$

We shall construct below certain $E(3,8)$-morphisms between the modules $M(p,q;r,y_X)$. This will imply that all modules $I(p,q;r,y)$ on the list are degenerate. The proof of the fact that the list is complete will be published elsewhere.

The theorem means that all the degenerate generalized Verma modules over $E(3,8)$ are in fact the direct summands of induced modules $M(V_X)$, $X=A,B,C,D$:

$$\begin{aligned}
M(V_X) &= \bigoplus_{m,n\in\mathbb{Z}} M(V_X^{m,n}),\ \text{where}\\
V_X^{m,n} &= \left\{ f\,\mathbf{1}_X \mid\ (\sum x_i\partial_i)f=mf,\ (\sum z_a\partial_a)f=nf \right\},
\end{aligned}$$

(we normalize degree of $\mathbf{1}_X$ as $(0,0)$).

We construct morphisms between these modules with the help of Proposition 1.1. As in the $E^\flat$ case [KR2], introduce the following operators on $M(\mathrm{Hom}(V_X,V_X))$:

$$\begin{aligned}
\triangledown &= \Delta^+\delta_+ + \Delta^-\delta_- = \delta_1\partial_1+\delta_2\partial_2+\delta_3\partial_3\,,\ \text{where}\\
\Delta^\pm &= \sum_{i=1}^{3} d_i^\pm\otimes\partial_i\,,\ \delta_i=\sum_{\alpha=\pm} d_i^a\otimes\partial_a\,.
\end{aligned}$$

Proposition 3.2. *(a) The element $\triangledown$ gives a well-defined morphism $M(V_X)\to M(V_X)$, $X=A,B,C,D$, by formula (1.2).*

(b) $\triangledown^2=0$.

Proof. The proof of (b) is the same as in [KR2]. In order to prove (a), we have to check conditions (1.4a) and (1.4b). It is obvious that $\Delta^\pm$ (resp. δ_i) are $s\ell_3(\mathbb{C})$-(resp. $s\ell_2(\mathbb{C})$-) invariant. Using both formulas for $\triangledown$, we conclude that it is $\mathfrak{g}_0$-invariant, proving (1.4a). In order to check (1.4b), first note that

$$e_0'\triangledown = (f_2\partial_1\partial_+ - f_{12}\partial_2\partial_+) = (x_3\partial_2\partial_1 - x_3\partial_1\partial_2)\,\partial_+ = 0\,.$$

Now

$$\begin{aligned}
e_0^\sharp\triangledown &= h_0^\sharp\partial_1\partial_+ + f_1\partial_2\partial_+ + f_{12}\partial_3\partial_1 - f_3\partial_1\partial_-\\
&= (x_1\partial_1 - z_+\partial_+ + T)\,\partial_1\partial_+ + x_2\partial_1\partial_2\partial_+ + x_3\partial_1\partial_3\partial_+ - z_-\partial_+\partial_1\partial_-\\
&= (x_1\partial_1 - z_+\partial_+ + T + x_2\partial_2 + x_3\partial_3 - z_-\partial_-)\,\partial_1\partial_+ = 0\,,
\end{aligned}$$

where we use (3.6) to check that

$$h_0^\sharp = \tfrac{2}{3}h_1+\tfrac{1}{3}h_2-\tfrac{1}{2}h_3+\tfrac{1}{2}Y^\sharp = x_1\partial_1 - z_+\partial_+ + T\,. \tag{3.7}$$

□

Let $M_{X'}=M(V_{X'})$, where:

$$\begin{aligned}
V_{A'} &= \mathbb{C}[x_1,x_2,x_3]\mathbf{1}_A = \oplus_{p\geq 0}V_A^{p,0}\,,\ V_{B'}=\mathbb{C}[x_1,x_2,x_3]\mathbf{1}_B=\oplus_{p\geq 0}V_B^{p,0}\\
V_{C'} &= \mathbb{C}[\partial_1,\partial_2,\partial_3]\mathbf{1}_C = \oplus_{q\geq 0}V_C^{-q,0}\,,\ V_{D'}=\mathbb{C}[\partial_1,\partial_2,\partial_3]\mathbf{1}_D=\oplus_{q\geq 0}V_D^{-q,0}
\end{aligned} \tag{3.8}$$

and let

$$\nabla_2 = \Delta^-\Delta^+ = d_1^-\Delta^+\partial_1 + d_2^-\Delta^+\partial_2 + d_3^-\Delta^+\partial_3\,. \tag{3.9}$$

We define the morphism $\nabla_2 : M_{A'} \to M_{B'}$ by extending the map defined by ∇_2 as follows

$$\begin{aligned} V_{A'} \xrightarrow{\sim} \mathbb{C}[x_1,x_2,x_3] &\longrightarrow U(L_-)\otimes\mathbb{C}[x_1,x_2,x_3]\mathbf{1}_B \simeq U(L_-)\otimes V_{B'}\,, \\ f\mathbf{1}_A \;\mapsto\; f \;&\mapsto\; \nabla_2 f\mathbf{1}_B\,. \end{aligned} \tag{3.10}$$

In order to apply Proposition 1.1, we have to check conditions (1.4a) and (1.4b) for ∇_2. As before, condition (1.4a) obviously holds. Now

$$e_0'\nabla_2\mathbf{1}_B = -\sum_i d_i^-(f_2\partial_1\partial_- - f_{12}\partial_2)\partial_i f\mathbf{1}_B = 0$$

because $f_2\partial_1 - f_{12}\partial_2 = x_3\partial_2\partial_1 - x_3\partial_1\partial_2 = 0$. Furthermore:

$$\begin{aligned} e_0^\sharp\nabla_2 f\mathbf{1}_B &= \left(-\sum_i d_i^-(h_0^\sharp\partial_1 + f_1\partial_2 + f_{12}\partial_3)\partial_i - f_3\Delta^+\partial_1\right) f\mathbf{1}_B \\ &= -\left(\sum_i d_i^-(x_1\partial_1 - z_+\partial_+ + T + x_2\partial_2 + x_3\partial_3)\partial_1\partial_2 - \Delta^-\partial_1 - \Delta^+\partial_1 f_3\right) f\mathbf{1}_B\,. \end{aligned}$$

As $z_\pm\partial_\pm f\mathbf{1}_B = fz_\pm\partial_\pm\mathbf{1}_B = f(-1+\partial_\pm z_\pm)\mathbf{1}_B = -f\mathbf{1}_B$, and $f_3 f\mathbf{1}_B = 0$, we conclude that

$$\begin{aligned} -e_0^\sharp\nabla_2 f\mathbf{1}_B &= \sum_i d_i^-(x_1\partial_1 + x_2\partial_2 + x_3\partial_3 - z_+\partial_+ + T + 1) f\mathbf{1}_B \\ &= \sum_i d_i^-(z_-\partial_- + 1) f\mathbf{1}_B = 0\,. \end{aligned}$$

Thus Proposition 1.1 applies and we get the morphism $\nabla_2 : M_{A'} \to M_{B'}$.

In exactly the same fashion we construct the morphism $\nabla_2 : M_{C'} \to M_{D'}$ by taking $f \in \mathbb{C}[\partial_1,\partial_2,\partial_3]$.

Thus we have proved part (a) of the following proposition; part (b) was checked in [KR2].

Proposition 3.3. *(a) Formulae (3.9) and (3.10) define the morphisms $\nabla_2 : M_{A'} \to M_{B'}$, $\nabla_2 : M_{C'} \to M_{D'}$ of $E(3,8)$-modules.*

(b) $\nabla\nabla_2 = 0$, $\nabla_2\nabla = 0$.

Similarly we can construct morphisms with the help of the element

$$\nabla_3 = \delta_1\delta_2\delta_3 = \sum_{a,b,c} d_1^a d_2^b d_3^c \otimes \partial_a\partial_b\partial_c\,,\quad (a,b,c = +,-)\,. \tag{3.11}$$

Let us consider modules $M_{X''} = M(V_{X''})$, where

$$\begin{aligned} V_{A''} &= \mathbb{C}[z_+,z_-]\mathbf{1}_A = \oplus_{r\geq 0} V_A^{0,r}\,,\; V_{B''} = \mathbb{C}[\partial_+,\partial_-]\mathbf{1}_B = \oplus_{r\geq 0} V_B^{0,-r}\,, \\ V_{C''} &= \mathbb{C}[z_+,z_-]\mathbf{1}_C = \oplus_{r\geq 0} V_B^{0,r}\,,\; V_{D''} = \mathbb{C}[\partial_+,\partial_-]\mathbf{1}_D = \oplus_{r\geq 0} V_D^{0,-r}\,. \end{aligned}$$

We construct morphisms $\nabla_3 : M_{A''} \to M_{C''}$ and $\nabla_3 : M_{B''} \to M_{D''}$ by extending the maps $\nabla_3' : V_{A''} \to U(L_-)\otimes V_{C''}$, $\nabla_3'' : V_{B''} \to U(L_-)\otimes V_{D''}$ given by the left and right diagrams below:

$$\begin{array}{ccc} \mathbb{C}[z_a]\cdot\mathbf{1}_A & \xrightarrow{\sim} & \mathbb{C}[z_+,z_-] \\ & & \big\downarrow{\scriptstyle \nabla_3} \\ & & U(L_-)\otimes(\mathbb{C}[z_+,z_-]\mathbf{1}_C) \end{array} \qquad \begin{array}{ccc} \mathbb{C}[\partial_a]\cdot\mathbf{1}_B & \xrightarrow{\sim} & \mathbb{C}[\partial_+,\partial_-] \\ & & \big\downarrow{\scriptstyle \nabla_3} \\ & & U(L_-)\otimes(\mathbb{C}[\partial_+,\partial_-]\mathbf{1}_D)\,. \end{array} \tag{3.12}$$

Here the horizontal maps are naturally $s\ell_3(\mathbb{C})\oplus s\ell_2(\mathbb{C})$-isomorphisms, but we have to define the action of Y on the target demanding the map to be a $\mathfrak{g}_0$-isomorphism. With this in mind we have to check that Y commutes with ∇_3.

We shall use the Einstein summation convention argument for the vertical maps ∇_3 given by (3.12). Then for $f\in\mathbb{C}[z_+,z_-]$ we have $Y(f\mathbf{1}_A)=(\deg f)f\mathbf{1}_A$ and

$$\begin{aligned} Y(d_1^a d_2^b d_3^c\otimes\partial_a\partial_b\partial_c f\mathbf{1}_C) &= d_1^a d_2^b d_3^c\otimes(-1+Y^\sharp)\partial_1\partial_b\partial_c f\mathbf{1}_C\\ &= d_1^a d_2^b d_3^c\otimes\partial_a\partial_b\partial_c f(-4+\deg f+Y^\sharp)\mathbf{1}_C\\ &= (\deg f)\cdot d_1^a d_2^b d_3^c\otimes\partial_a\partial_b\partial_c f\mathbf{1}_C\,. \end{aligned}$$

Similarly for $f\in\mathbb{C}[\partial_+,\partial_-]$, we have $Y(f\mathbf{1}_B)=(-\deg f-2)f\mathbf{1}_B$ and

$$\begin{aligned} Y(d_1^a d_2^b d_3^c\otimes\partial_a\partial_b\partial_c f\mathbf{1}_D) &= d_1^a d_2^b d_3^c\otimes\partial_a\partial_b\partial_c f(-4-\deg f+Y^\sharp)\mathbf{1}_D\\ &= (-4-\deg f+2)d_1^a d_2^b d_3^c\otimes\partial_a\partial_b\partial_c f\mathbf{1}_D\,, \end{aligned}$$

where $Y^\sharp$ defined by (3.6). Thus we get the commutativity.

One meets no problem checking $e_0'\nabla_3=0$, but we consider calculations for $e_0^\sharp\nabla_3$ in more detail. If $f\in\mathbb{C}[z_+,z_-]$, then

$$e_0(\nabla_3 f\mathbf{1}_C)=h_0^\sharp d_2^b d_3^c\otimes\partial_+\partial_b\partial_c f\mathbf{1}_C-f_3 d_2^b d_3^c\otimes\partial_-\partial_b\partial_c f\mathbf{1}_C\,,$$

because $d_1^a(x_2\partial_1)d_3^c\otimes\partial_a\partial_+\partial_c f\mathbf{1}_C=d_1^a d_2^b(x_3\partial_1)\otimes\partial_a\partial_b\partial_+ f\mathbf{1}_C=0$. Now $f_3(d_2^b d_3^c\otimes\partial_b\partial_c)=(d_2^b d_3^c\otimes\partial_b\partial_c)f_3$ and $h_0^\sharp(d_2^b d_3^c\otimes\partial_b\partial_c)=(d_2^b d_3^c\otimes\partial_b\partial_c)(h_0^\sharp-2)$, where $h_0^\sharp=\frac{2}{3}h_1+\frac{1}{3}h_2-\frac{1}{2}h_3+\frac{1}{2}Y^\sharp$, and again $Y^\sharp$ is defined by (3.6). Therefore

$$\begin{aligned} e_0^\sharp(\nabla_3 f\mathbf{1}_C) &= (d_2^b d_3^c\otimes\partial_b\partial_c)(h_0^\sharp\partial_+-2\partial_+-z_+\partial_+\partial_-)f\mathbf{1}_C\\ &= (d_2^b d_3^c\otimes\partial_b\partial_c)(h_0^\sharp-z_-\partial_--2)\partial_+ f\mathbf{1}_C\\ &= (d_2^b d_3^c\otimes\partial_b\partial_c)(-x_2\partial_2-x_3\partial_3-2)\partial_+ f\mathbf{1}_C\\ &= (d_2^b d_3^c\otimes\partial_b\partial_c)(-\partial_2 x_2-\partial_3 x_3)\partial_+ f\mathbf{1}_C=0\,. \end{aligned}$$

The calculations in the case $f\in\mathbb{C}[\partial_+,\partial_-]$ are very much the same. So we have proved part (a) of the following proposition; part (b) was checked in [KR2]

Proposition 3.4. *(a) Formulae (3.11) and (3.12) define the morphisms $\nabla_3: M_{A''}\to M_{D''}$ and $M_{B''}\to M_{D''}$ of $E(3,8)$-modules.*

(b) $\nabla\cdot\nabla_3=0\,,\quad \nabla_3\cdot\nabla=0.$

Furthermore, there are $E(3,8)$-module morphisms

$$\begin{aligned} \nabla_4' &: M(00;2;y_A)\to M(01;1;y_D) \text{ and}\\ \nabla_4'' &: M(10;0;y_A)\to M(00;2;y_D) \end{aligned}$$

defined by formulae (2.14) and (2.17) from [KR2], applied to $E(3,8)$. Arguments similar to those in [KR2] show that these are indeed well-defined morphisms.

Thus far we have constructed $E(3,8)$-homomorphisms ∇, ∇_2, ∇_3, ∇_4', and ∇_4'' between generalized Verma modules. Note that these maps have degree 1, 2, 3 and 4, respectively with respect to the $\mathbb{Z}$-gradation of $U(L_-)$ induced by that of $E(3,8)$.

As in the case of $E(3,6)$ [KR2], all these maps are illustrated in Figure 1. The nodes in the quadrants A,B,C,D represent generalized Verma modules $M(p,0;r;y_X)$ if $X=A$ or B, and $M(0,q;r;y_X)$, if $X=C$ or D. The plain arrows represent ∇, the dotted arrows represent ∇_2, the interrupted arrows represent ∇_3 and the bold arrows represent ∇_4' and ∇_4''.

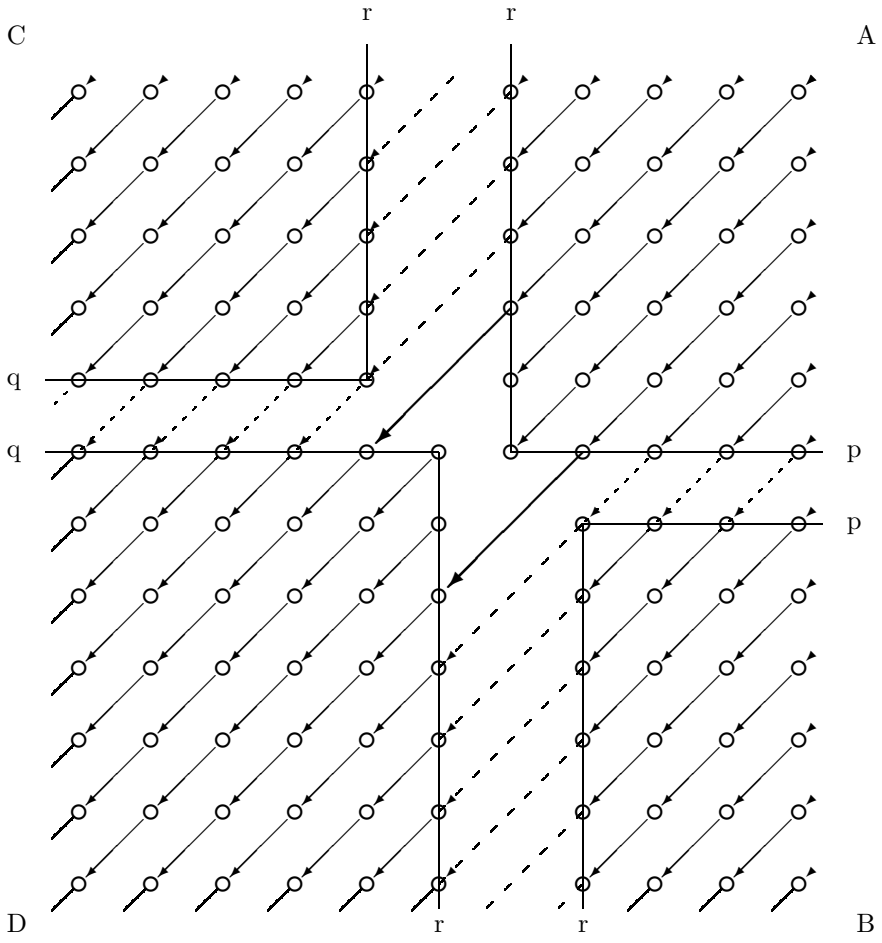

FIGURE 1.

Note that the generalized Verma modules $M(00;1;y_A)$ and $M(00;1;y_D)$ are isomorphic since $y_A = y_D = 1$. We shall identify them. This allows us to construct the $E(3,8)$-module homomorphism

$$\widetilde{\nabla} : M(00;1;y_A) \to M(01;2;y_D)\,,$$

which is NOT represented in Figure 1.

Note that $I(00;1;y_A) = I(00;1;y_D)$ is the coadjoint $E(3,8)$-module. It follows from the above propositions that if we remove the module $M(00;1;y_D)$ from Figure 1, and draw $\widetilde{\nabla}$ then all sequences in the modified Figure 1 become complexes. We denote by $H_A^{p,-r}$, $H_B^{p,r}$, $H_C^{-q,r}$ and $H_D^{-q,-r}$ the homology of these complexes at the position of $M(pq;r;y_X)$, $X = A, B, C, D$.

Theorem 3.5. *(a) The kernels of all maps* ∇, ∇_2, ∇_3, ∇'_4, ∇''_4, $\widetilde{\nabla}$ *are maximal submodules.*

(b) The homology $H_X^{m,n}$ is zero except for six cases listed (as $E(3,8)$-modules) below:

$$\begin{aligned} H_A^{0,0} &= \mathbb{C}\,, \quad H_A^{1,1} = I(10;0;-\tfrac{4}{3})\,, \\ H_A^{1,0} &= H_D^{0,-2} = I(00;0;-2)\,, \\ H_D^{-1,-1} &= H_D^{-1,-2} = I(00;1;1)\oplus\mathbb{C}\,. \end{aligned}$$

The proof is similar to that of the analogous $E(3,6)$-result in [KR2]. Note that this theorem gives the following explicit construction of all degenerate irreducible $E(3,8)$-modules:

$$I(pq;r;y_X) = M(pq;r;y_X)/\operatorname{Ker}\nabla\,,$$

where ∇ is the corresponding map in the modified Figure 1.

4. **Three series of degenerate Verma modules over $E(5,10)$**

As in [KR2] and in § 2, we use for the odd elements of $E(5,10)$ the notation $d_{ij} = dx_i \wedge dx_j$ $(i,j = 1,2,\dots,5)$; recall that we have the following commutation relation ($f,g \in \mathbb{C}[[x_1,\dots,x_5]]$):

$$[fd_{jk}, gd_{\ell m}] = \epsilon_{ijk\ell m}\partial_i\,,$$

where $\epsilon_{ijk\ell m}$ is the sign of the permutation $ijk\ell m$ if all indices are distinct and 0 otherwise.

Recall that the Lie superalgebra $E(5,10)$ carries a unique consistent irreducible $\mathbb{Z}$-gradation $E(5,10) = \oplus_{j\geq -2} p_j$. It is defined by:

$$\deg x_i = 2 = -\deg\partial_i\,,\ \deg d_{ij} = -1\,.$$

One has: $p_0 \simeq s\ell_5(\mathbb{C})$ and the p_0-modules occurring in the L_- part are:

$$\begin{aligned} p_{-1} &= \langle d_{ij} \mid i,j = 1,\dots,5\rangle \simeq \Lambda^2\mathbb{C}^5\,, \\ p_{-2} &= \langle \partial_i \mid i = 1,\dots,5\rangle \simeq \mathbb{C}^{5*}\,. \end{aligned}$$

Recall also that p_1 consist of closed 2-forms with linear coefficients, that p_1 is an irreducible p_0-module and $p_j = p_1^j$ for $j \geq 1$.

We take for the Borel subalgebra of p_0 the subalgebra of the vector fields $\langle \sum_{i\leq j} a_{ij}x_i\partial_j | a_{ij} \in \mathbb{C}\,,\ \operatorname{tr}(a_{ij}) = 0\rangle$, and denote by $F(m_1,m_2,m_3,m_4)$ the finite-dimensional irreducible p_0-module with highest weight (m_1,m_2,m_3,m_4). We let

$$M(m_1,m_2,m_3,m_4) = M(F(m_1,m_2,m_3,m_4))$$

denote the corresponding generalized Verma module over $E(5,10)$.

Conjecture 4.1. *The following is a complete list of generalized Verma modules over $E(5,10)$ $(m,n \in \mathbb{Z}_+)$:*

$$M(m,n,0,0)\,,\ M(0,0,m,n) \text{ and } M(m,0,0,n)\,.$$

In this section we construct three complexes of generalized $E(5,10)$ Verma modules which shows, in particular, that all modules from the list given by Conjecture 4.1 are degenerate. We let:

$$S_A = S(\mathbb{C}^5 + \Lambda^2\mathbb{C}^5)\,,\ S_B = S(\mathbb{C}^{5*} + \Lambda^2\mathbb{C}^{5*})\,,\ S_C = S(\mathbb{C}^5 + \mathbb{C}^{5*})\,.$$

Denote by x_i $(i = 1,\dots,5)$ the standard basis of $\mathbb{C}^5$ and by $x_{ij} = -x_{ji}$ $(i,j = 1,\dots,5)$ the standard basis of $\Lambda^2\mathbb{C}^5$. Let x_i^* and $x_{ij}^* = -x_{ji}^*$ be the dual bases of $\mathbb{C}^{5*}$ and $\Lambda^2\mathbb{C}^{5*}$, respectively. Then S_A is the polynomial algebra in 15 indeterminates x_i and x_{ij}, S_B is the

polynomial algebra in 15 indeterminates x_i^* and x_{ij}^* and S_C is the polynomial algebra in 10 indeterminates x_i and x_i^*.

Given two irreducible p_0-modules E and F, we denote by $(E\otimes F)_{\text{high}}$ the highest irreducible component of the p_0-module $E\otimes F$. If $E=\oplus_i E_i$ and $F=\oplus_j F_j$ are direct sums of irreducible p_0-modules, we let $(E\otimes F)_{\text{high}}=\oplus_{i,j}(E_i\otimes F_j)_{\text{high}}$. If E and F are again irreducible p_0-modules, then $S(E\oplus F)=\oplus_{m,n\in\mathbb{Z}_+}S^mE\otimes S^nF$, and we let $S_{\text{high}}(E\oplus F)=\oplus_{m,n\in\mathbb{Z}_+}(S^mE\otimes S^nF)_{\text{high}}$. We also denote by $S_{\text{low}}(E\oplus F)$ the complement to $S_{\text{high}}(E\oplus F)$.

It is easy to see that we have as p_0-modules:

$$\begin{aligned} S_{A,\text{high}} &\simeq \oplus_{m,n\in\mathbb{Z}_+}F(m,n,0,0)\,,\\ S_{B,\text{high}} &\simeq \oplus_{m,n\in\mathbb{Z}_+}F(0,0,m,n)\,,\\ S_{C,\text{high}} &\simeq \oplus_{m,n\in\mathbb{Z}_+}F(m,0,0,n)\,. \end{aligned}$$

Introduce the following operators on the spaces $M(\text{Hom}(S_X,S_X))$, $X=A$, B or C:

$$\nabla_X=\sum_{i,j=1}^5 d_{ij}\otimes\theta_{ij}^X\,,$$

where

$$\theta_{ij}^A=\frac{d}{dx_{ij}}\,,\ \theta_{ij}^B=x_{ij}^*\,,\ \theta_{ij}^C=x_i^*\frac{d}{dx_j}-x_j^*\frac{d}{dx_i}\,.$$

It is immediate to see that $p_0\cdot\nabla_X=0$. In order to apply Proposition 1.1, we need to check that

$$p_1\cdot\nabla_X=0\,. \tag{4.1}$$

This is indeed true in the case $X=C$, but it is not true in the cases $X=A$ and B. In fact (4.1) applied to $f\in S_X$, $X=A$ or B, is equivalent to the following equations, respectively $(a,b,c,d=1,\dots,5)$:

$$\left(\frac{d}{dx_{ab}}\frac{d}{dx_{cd}}-\frac{d}{dx_{ac}}\frac{d}{dx_{bd}}+\frac{d}{dx_{ad}}\frac{d}{dx_{bc}}\right)f = 0\,, \tag{4.2}$$

$$(x_{ab}^*x_{cd}^*-x_{ac}^*x_{bd}^*+x_{ad}^*x_{bc}^*)\,f = 0\,. \tag{4.3}$$

It is not difficult to check the following lemma.

Lemma 4.2. *(a) The subspace of S_A defined by equations (4.2) is $S_{A,\text{high}}$.*
(b) Equations (4.3) hold in $S_B/S_{B,\text{low}}$.
(c) Equation $\nabla_X^2=0$ is equivalent to the system of equations $(a,b,c,d=1,\dots,5)$:

$$\theta_{ab}\theta_{cd}-\theta_{ac}\theta_{bd}+\theta_{ad}\theta_{bc}=0\,.$$

We let:

$$V_A=S_{A,\text{high}}\,,\ V_{B(\text{resp. }C)}=S_{B(\text{resp. }C)}/S_{B(\text{resp. }C),\text{low}}$$

The above discussion implies

Proposition 4.3. *(a) The operators ∇_X define $E(5,10)$-morphisms $M(V_X)\to M(V_X)$ $(X=A,B$ or $C)$.*
(b) $\nabla_X^2=0$ $(X=A,B$ or $C)$.
(c) $\nabla_X=0$ iff $X=A$ and $n=0$, or $X=C$ and $m=0$.

The non-zero maps ∇_X are illustrated in Figure 2. The nodes in the quadrants A, B and C represent generalized Verma modules $M(m,n,0,0)$, $M(0,0,m,n)$ and $M(m,0,0,n)$, respectively. The arrows represent the $E(5,10)$-morphisms ∇_X, $X = A$, B or C in the respective quadrants.

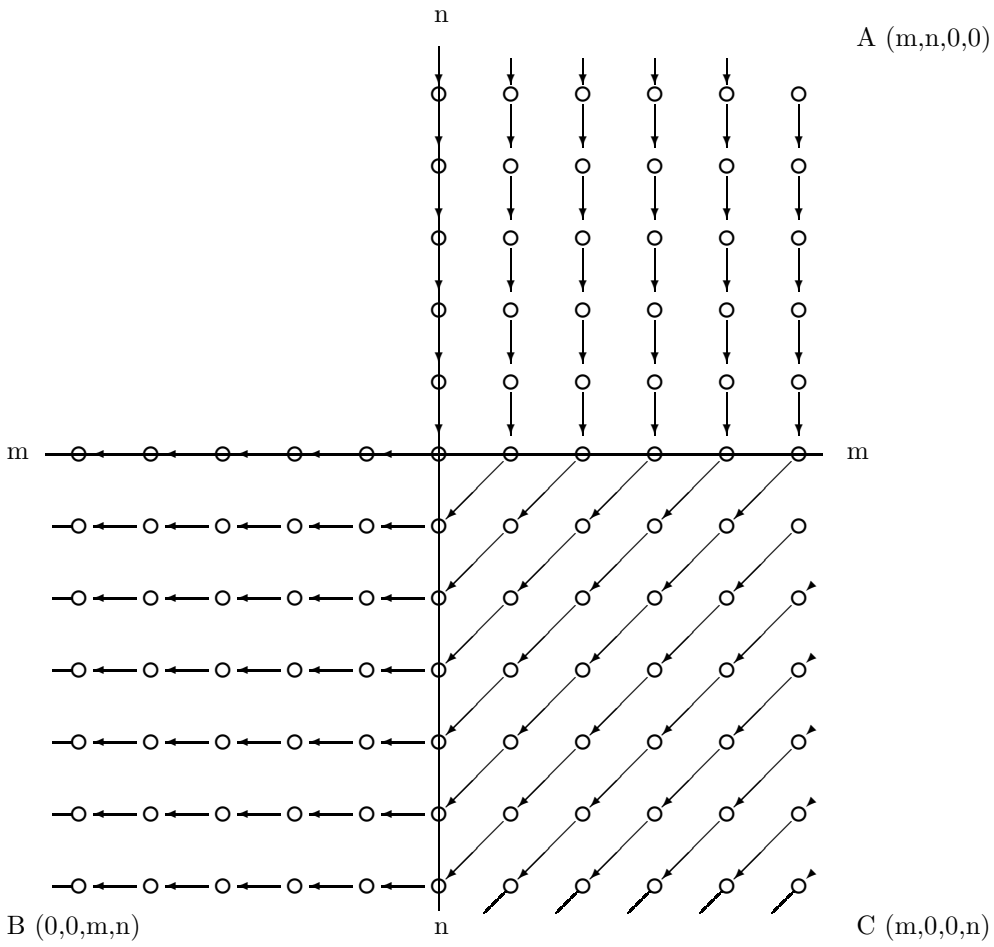

FIGURE 2.

The following theorem summarizes our results on degenerate $E(5,10)$-modules.

Theorem 4.4. *(a) Each connected component in Figure 2 is a complex of $E(5,10)$-modules. (b) The kernels of all morphisms in these complexes are irreducible maximal submodules.*
